- Consider a certain *experiment*, such as throwing a die; this experiment can have different results, we call each result an *outcome*
- The set of all possible outcomes of an experiment is called the sample space, Ω
- An *event* is a set of elements or subset of Ω
- Probability theory has to do with measuring and combining the *degrees of plausibility* of events.

Interpretations (1)

Classical: probability has to do with equiprobable events; if a certain experiment has N possible outcomes, the probability of each outcome is $1/N$.

Logical: probability is a measure of rational belief; that is, according to the available evidence, a rational person will have a certain belief regarding an event, which will define its probability.

Subjective: probability is a measure of the personal degree of belief in a certain event; this could be measured in terms of a betting factor –the probability of a certain event for an individual is related to how much that person is willing to bet on that event.

Frequency: probability is a measure of the number of occurrences of an event given a certain experiment, when the number of repetitions of the experiment tends to infinity.

Propensity: probability is a measure of the number of occurrences of an event under repeatable conditions; even if the experiment only occurs once.

Main approaches

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- Objective (classical, frequency, propensity): probabilities exist in the *real* world and can be measured.
- Epistemological (logical, subjective): probabilities have to do with human knowledge, they are measures of belief.
- Both approaches follow the same mathematical axioms defined below; however there are differences in the manner in which probability is applied

Logical Approach

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- Define probabilities in terms of the degree of plausibility of a certain proposition given the available evidence – desiderata:
 - Representation by real numbers.
 - Qualitative correspondence with common sense.
 - Consistency.

Based on these intuitive principles, we can derive the three axioms of probability:

- ① $P(A)$ is a continuous monotonic function in $[0, 1]$.
 - ② $P(A, B | C) = P(A | C)P(B | A, C)$ (product rule).
 - ③ $P(A | B) + P(\neg A | B) = 1$ (sum rule).
- Probabilities are always defined with respect to certain context or *background* knowledge: $P(A | B)$ (sometimes the background is omitted for simplicity).

Sum rule

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- The probability of the disjunction (logical sum) of two propositions is given by the *sum rule*:
$$P(A + B | C) = P(A | C) + P(B | C) - P(A, B | C)$$
- If propositions A and B are mutually exclusive given C , we can simplify it to:
$$P(A + B | C) = P(A | C) + P(B | C)$$
- Generalized for N mutually exclusive propositions to:
$$P(A_1 + A_2 + \dots + A_N | C) = P(A_1 | C) + P(A_2 | C) + \dots + P(A_N | C)$$

Conditional Probability

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- $P(H | B)$ conditioned only on the background B is called *a priori* or prior probability;
- Once we incorporate some additional information D we call it a *posterior* probability, $P(H | D, B)$
- The conditional probability can be defined as (for simplicity we omit the background):
$$P(H | D) = P(H, D) / P(D)$$

Bayes Rule

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

From the product rule we obtain:

$$P(D, H | B) = P(D | H, B)P(H | B) = P(H | D, B)P(D | B) \quad (1)$$

From which we obtain:

$$P(H | D, B) = \frac{P(H | B)P(D | H, B)}{P(D | B)} \quad (2)$$

This last equation is known as the *Bayes rule*

The term $P(H | B)$ is the *prior* and $P(D | H, B)$ is the *likelihood*

Independence

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- In some cases the probability of H is not influenced by the knowledge of D , so it is said that H and D are *independent*, therefore $P(H, D | B) = P(H | B)$
- The product rule can be simplified to:
$$P(A, B | C) = P(A | C)P(B | C)$$

Conditional Independence

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- If two propositions are independent given only the background information they are *marginally* independent; however if they are independent given some additional evidence, E , then they are *conditionally* independent: $P(A, D | B, E) = P(H | B, E)$
- Example: A represents the proposition *watering the garden*, D the *weather forecast* and E *raining*

Chain Rule

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- The probability of a conjunction of N propositions, that is $P(A_1, A_2, \dots, A_N | B)$, is usually called the *joint* probability
- If we generalize the product rule to N propositions we obtain what is known as the *chain* rule:

$$P(A_1, A_2, \dots, A_N | B) = P(A_1 | A_2, A_3, \dots, A_N, B)P(A_2 | A_3, A_4, \dots, A_N, B) \cdots P(A_N | B)$$

- Conditional independence relations between the propositions can be used to simplify this product

Total Probability

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- Consider a partition, $B = \{B_1, B_2, \dots, B_n\}$, on the sample space Ω , such that $\Omega = B_1 \cup B_2 \cup \dots \cup B_n$ and $B_i \cap B_j = \emptyset$
- A is equal to the union of its intersections with each event B_i , $A = (B_1 \cap A) \cup (B_2 \cap A) \cup \dots \cup (B_n \cap A)$

- Then:

$$P(A) = \sum_i P(A | B_i)P(B_i) \quad (3)$$

- Given the total probability rule, we obtain Bayes theorem:

$$P(B | A) = \frac{P(B)P(A | B)}{\sum_i P(A | B_i)P(B_i)} \quad (4)$$

Discrete Random Variables

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- Consider a finite set of exhaustive and mutually exclusive propositions
- If we assign a numerical value to each proposition x_i , then X is a *discrete random variable*
- The probabilities for all possible values of X , $P(X)$ is the probability distribution of X

Probability Distributions

- Uniform: $P(x_i) = 1/N$
- Binomial: assume we have an urn with N colored balls, red and black, of which M are red, so the fraction of red balls is $\pi = M/N$. We draw a ball at random, record its color, and return it to the urn, mixing the balls again (so that, in principle, each draw is independent from the previous one). The probability of getting r red balls in n draws is:

$$P(r | n, \pi) = \binom{n}{r} \pi^r (1 - \pi)^{n-r}, \quad (5)$$

where $\binom{n}{r} = \frac{n!}{r!(n-r)!}$.

Mean and Variance

- The expected value or *expectation* of a discrete random variable is the average of the possible values, weighted according to their probabilities:

$$E(X | B) = \sum_{i=1}^N P(x_i | B)x_i \quad (6)$$

- The *variance* is defined as the expected value of the square of the variable minus its expectation:

$$\text{Var}(X | B) = \sum_{i=1}^N P(x_i | B)(x_i - E(X))^2 \quad (7)$$

- The square root of the variance is known as the standard deviation

Continuous random variables

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- If we have a continuous variable X , we can divide it into a set of mutually exclusive and exhaustive intervals, such that $P = (a < X \leq b)$ is a proposition, thus the rules derived so far apply to it
- A *continuous random variable* can be defined in terms of a *probability density function*, $f(X | B)$, such that:

$$P(a < X \leq b | B) = \int_a^b f(X | B) dx \quad (8)$$

- The probability density function must satisfy $\int_{-\infty}^{\infty} f(X | B) dx = 1$

Normal Distribution

A Normal distribution is denoted as $N(\mu, \sigma^2)$, where μ is the *mean* (center) and σ is the *standard deviation* (spread); and it is defined as:

$$f(X | B) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left\{-\frac{1}{2\sigma^2}(x - \mu)^2\right\} \quad (9)$$

Exponential Distribution

The exponential distribution is denoted as $Exp(\beta)$; it has a single parameter $\beta > 0$, and it is defined as:

$$f(X | B) = \frac{1}{\beta} e^{-x/\beta}, x > 0 \quad (10)$$

Cumulative Distribution

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- The cumulative distribution function of a random variable, X , is the probability that $X \leq x$. For a continuous variable, it is defined in terms of the density function as:

$$F(X) = \int_{-\infty}^x f(X) \quad (11)$$

- In the case of discrete variables, the cumulative probability, $P(X \leq x)$ is defined as:

$$\mathbf{P}(x) = \sum_{X=-\infty}^{X=x} P(X) \quad (12)$$

Cumulative Distribution Properties

Introduction

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- In the interval $[0, 1]$: $0 \leq F(X) \leq 1$
- Non-decreasing: $F(X_1) < F(X_2)$ if $X_1 < X_2$
- Limits: $\lim_{x \rightarrow -\infty} = 0$ and $\lim_{x \rightarrow \infty} = 1$

2D Random Variables

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- Given two random variables, X and Y , their joint probability distribution is defined as $P(x, y) = P(X = x \wedge Y = y)$.
- For example, X might represent the number of products completed in one day in product line one, and Y the number of products completed in one day in product line two
- $P(X, Y)$ must follow the axioms of probability, in particular: $0 \leq P(x, y) \leq 1$ and $\sum_x \sum_y P(X, Y) = 1$

2D Example

- Given two product lines, line one (X) may produce 1, 2 or 3 products per day, and line two (Y), 1 or 2 products, according to the following joint probability distribution:

	$X=1$	$X=2$	$X=3$
$Y=1$	0.1	0.3	0.3
$Y=2$	0.2	0.1	0

Marginal and conditional probabilities

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- Given the joint probability distribution, $P(X, Y)$, we can obtain the distribution for each individual random variable:

$$P(x) = \sum_y P(X, Y); P(y) = \sum_x P(X, Y) \quad (13)$$

- From the previous example -
 $P(X = 2) = 0.3 + 0.1 = 0.4$ and
 $P(Y = 1) = 0.1 + 0.3 + 0.3 = 0.7$.
- Conditional probabilities of X given Y and vice-versa:

$$P(x | y) = P(x, y)/P(y); P(y | x) = P(x, y)/P(x) \quad (14)$$

Independence

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- Two random variables, X , Y are independent if their joint probability distribution is equal to the product of their marginal distributions (for all values of X and Y):

$$P(X, Y) = P(X)P(Y) \rightarrow \text{Independent}(X, Y) \quad (15)$$

Correlation

- It is a measure of the degree of linear relation between two random variables, X , Y and is defined as:

$$\rho(X, Y) = E\{[X - E(X)][Y - E(Y)]\}/(\sigma_X\sigma_Y) \quad (16)$$

where $E(X)$ is the expected value of X and σ_X its standard deviation.

- The correlation is in the interval $[-1, 1]$; a positive correlation indicates that as X increases, Y tends to increase; and a negative correlation that as X increases, Y tends to decrease.
- A correlation of zero does not necessarily imply independence

Information Theory

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- Information theory originated in the area of communications, although it is relevant for many different fields
- Assume that we are communicating the occurrence of a certain event. Intuitively we can think that the amount of *information* from communicating an event is inverse to the probability of the event.

Formalization

- Assume we have a source of information that can send q possible messages, m_1, m_2, \dots, m_q ; where each message corresponds to an event with probabilities P_1, P_2, \dots, P_q
- $I(m)$ based on the probability of m - properties:
 - The information ranges from zero to infinity: $I(m) \geq 0$.
 - The information increases as the probability decreases: $I(m_i) > I(m_j)$ if $P(m_i) < P(m_j)$.
 - The information tends to infinity as the probability tends to zero: $I(m) \rightarrow \infty$ if $P(m) \rightarrow 0$.
 - The information of two messages is equal to the sum of that of the individual messages if these are independent: $I(m_i + m_j) = I(m_i) + I(m_j)$ if m_i independent of m_j .

- A function that satisfies the previous properties is the logarithm of the inverse of the probability, that is:

$$I(m_k) = \log(1/P(m_k)) \quad (17)$$

- It is common to use base two logarithms, so the information is measured in “bits”:

$$I(m_k) = \log_2(1/P(m_k)) \quad (18)$$

- For example, if we assume that the probability of the message m_r “raining in Puebla” is $P(m_r) = 0.25$, the corresponding information is $I(m_r) = \log_2(1/0.25) = 2$

Entropy

Introduction

Interpretations
of Probability

Basic Rules

Random
VariablesTwo Dimensional
Random VariablesInformation
Theory

References

- Given the definition of expected value, the average information of q message or entropy is defined as:

$$H(m) = E(I(m)) = \sum_{i=1}^{i=q} P(m_i) \log_2(1/P(m_i)) \quad (19)$$

- This can be interpreted as that on average H bits of information will be sent

Max and Min Entropy

Introduction

Interpretations
of Probability

Basic Rules

Random
Variables

Two Dimensional
Random Variables

Information
Theory

References

- When will H have its maximum and minimum values?
- Consider a binary source such that there are only two messages, m_1 and m_2 ; with $P(m_1) = p_1$ and $P(m_2) = p_2$. Given that there are only two possible messages, $p_2 = 1 - p_1$, so H only depends on one parameter, p_1 (or just p)
- For which values of p is H maximum and minimum?

- *Conditional entropy:*

$$H(X | y) = \sum_{i=1}^{i=q} P(X_i | y) \log_2 [1 / P(X_i | y)] \quad (20)$$

- *Cross entropy:*

$$H(X, Y) = \sum_X \sum_Y P(X, Y) \log_2 [P(X, Y) / P(X)P(Y)] \quad (21)$$

- The cross entropy provides a measure of the mutual information (dependency) between two random variables
